1983–84 Survey of Physics and Astronomy Bachelor's Degree Recipients

by Susanne D. Ellis

AIP Pub. No. 211.16 March 1985

Since the late 1970's the number of physics bachelor's degrees granted has shown a gradual increase each year and the class of 1984 is no exception. Astronomy degrees, on the other hand, did not exhibit a similar trend. The survey upon which this report is based collects information from individual degree recipients and focuses on their postbaccalaureate plans. Gathering data for over twenty years from physics bachelors and for almost ten years from astronomy bachelors enables us to present trends and interpret changes. Highlights of the information presented in this report are:

→ An increase in the proportion of women among the physics bachelors.

→ Fewer employment-oriented bachelors had accepted positions upon graduation.

→ Starting salaries paid by manufacturing industries rose only 3%.

The major career goals of physics bachelors fall into one of two categories: graduate study or employment, which for the class of 1984 indicate an almost even split. Both **Figure I** and **Table I** show the postbaccalaureate plans of physics bachelors for the past ten years and how small the changes were during that period. A further distinction included in **Figure I** is the relative proportion of bachelors who continue to study physics and those who switch to other disciplines of graduate study. Similarly, the employment-oriented graduates are divided into those entering civilian employment and those seeking a military career.

The numerical data for the bar graph of **Figure I** are presented in **Table I** which clearly indicates a leveling of the percentages of physics bachelors who enter graduate physics departments without interruption. Looking back to the class of 1975, the employment opportunities from the civilian sector appear to have improved steadily. The bottom row of **Table I** lists the total number of physics bachelor's degrees granted each year; data are derived from the departmental survey of Enrollments and Degrees.

**Percentage of women was adjusted for differential response rate.*

Major characteristics of new physics bachelors, as shown in **Table II**, can be identified more meaningfully when examined by subgroup. For example, looking at the age distributions of the graduates we find that employment-oriented bachelors tend to be older than those headed for graduate study. Traditionally, 22 was the most common age at which students completed their bachelor's degrees; however the data in **Table II** show that only half of the potential graduate students are age 22 and even fewer (37%) of the employment-oriented bachelors fall into that age group.

At the undergraduate level only six percent of the physics students are foreign; however, singling out those bachelors who have been accepted at graduate physics departments, we find that ten percent of them are foreign citizens. On the other hand employment-oriented bachelors include only two percent who are foreign.

Changes in characteristics from the previous year include a two percentage-point increase in the proportion of women as well as a small increase in U.S. minorities among the physics bachelors of 1984.

A major problem with the teaching of high school physics in the U.S. is that it is a local responsibility and no standard curriculum exists. Consequently there are many school districts that either do not offer physics at all, or do not offer it every year. To see what effect this situation had on those who completed physics bachelor's degrees, we asked what type of high school physics course, if any, the graduates had taken. Over two thousand individuals responded to that question. As shown in **Table III**, 17% of them indicated that they did not take any physics before entering college, a proportion which is slightly higher (20%) for physics bachelors who are women.

Table III. A comparison between men and women 1983–84 physics bachelors and their high school physics backgrounds.

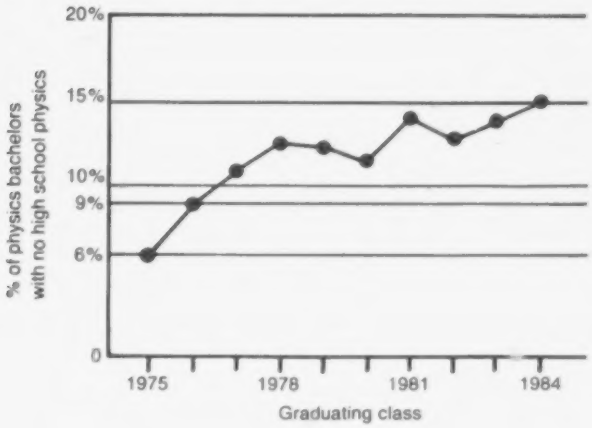
Figure II. Physics bachelors, entering graduate physics departments, who did not take high school physics, 1975 to 1984.



Since physicists are known to develop an interest in their discipline at an early age, we focused on the potential physicists among the physics bachelors to see what their high school physics backgrounds were. By "potential physicists" we mean those whose post-degree plan is graduate study in physics. Thus **Figure II** shows that back in 1975 only 6% of the potential physicists had not taken physics in high school, but by 1984 15% of the corresponding group fell into that category.

Having demonstrated in connection with **Table II** how the characteristics of a composite group can differ significantly from those of its component parts we apply a similar analysis in **Table IV** to the minority students among the physics bachelors. The postbaccalaureate plans of U.S. minority students as a whole are similar to those of all respondents in the class of 1984. However, by examining the plans of U.S. blacks and U.S. Orientals separately, we find that an above-average proportion of blacks seeks immediate employment, whereas above-average proportions of the Orientals enter graduate schools.

Different considerations should be applied to foreign minority students, who, like most foreign students, are in the U.S. on student visas which do not make them eligible for employment. Thus we find that a very large proportion of the foreign minorities (80%) plan to enter graduate school. As in past years, foreign Orientals are most likely to go on to physics graduate study.

Additional details on minorities are provided in **Table V**, which lists seven distinct minority groups and the numbers of physics bachelors who identified themselves with each group. The larger groups that are neither predominantly foreign nor predominantly U.S. are divided on the basis of citizenship and the following three characteristics are presented: sex, region and type of bachelor's institution. Thus the table indicates that U.S. blacks include the highest proportion of women and that they are concentrated in the four-year colleges. U.S. Orientals, on the other hand, tend to choose Ph.D.-granting institutions for their undergraduate studies. A conspicuous change from earlier years shown in **Table V** is the decrease in the number of Arab graduates. The 17 respondents included in this table represent a decline from 35 and 42 respondents in 1983 and 1982 respectively.

Table IV. Postbaccalaureate plans of U.S. and foreign minorities among the physics bachelors of the class of 1984.

Minorities	Postbaccalaureate plans: Graduate study: Physics	Graduate study: Other	Empl.	Total %	N

Graduate study status: part-time	6	6	7	10	12	17
Total number of full-time students	1332	1355	1475	1066	1066	1068

**The information was reported for September of each academic year.*

The most common type of support offered to first year graduate students is a teaching assistantship. **Table VI** is based on new physics bachelors who are interested in immediate full-time graduate study, and its data show that by studying physics rather than another graduate discipline, the student is twice as likely to be offered a teaching assistantship. Another major difference between the prospective physics graduate students and those switching to other disciplines is the proportion who report the use of personal funds. By combining "Employment (part-time)" and "Family, savings, loan," we find that only between 5% and 7% of the physics students were included in those categories, but over 35% of those interested in "other graduate study" reported these sources of support.

The lower portion of **Table VI** is based on a slightly larger group of new physics bachelors because it includes those who have accepted full-time employment and pursue graduate study on a part-time basis. In physics the part-time students comprise 6% or 7%, whereas those who enter "other graduate study" include between 10% and 17% part-time students.

Since almost half of the physics bachelors each year are interested in immediate employment, demand for them is an important piece of information to monitor annually. To accomplish that we ask each employment-oriented graduate for the number of job offers he or she received, which provides us with a scale of no offers, one offer, and multiple offers. **Table VII** presents these data consecutively for the years since 1980 and lists three years from the 1970's for comparison. It should be pointed out that "zero job offers" refers to the time immediately following graduation and should not be mistaken for a general unemployment rate. Thus an overall evaluation of the demand for physics bachelors is that close to 90% of the employment-oriented graduates accept positions either before or shortly after graduation; but ten years earlier the demand was considerably less.

Although postbaccalaureate plans have been discussed in connection with earlier figures and tables, the format of **Figure III** offers unique details. In particular it lists the major subjects of graduate study for those physics bachelors who chose a physics-related or another discipline for their graduate work. Also, it divides the employment-oriented graduates into categories which specify different stages of entry into the labor force.

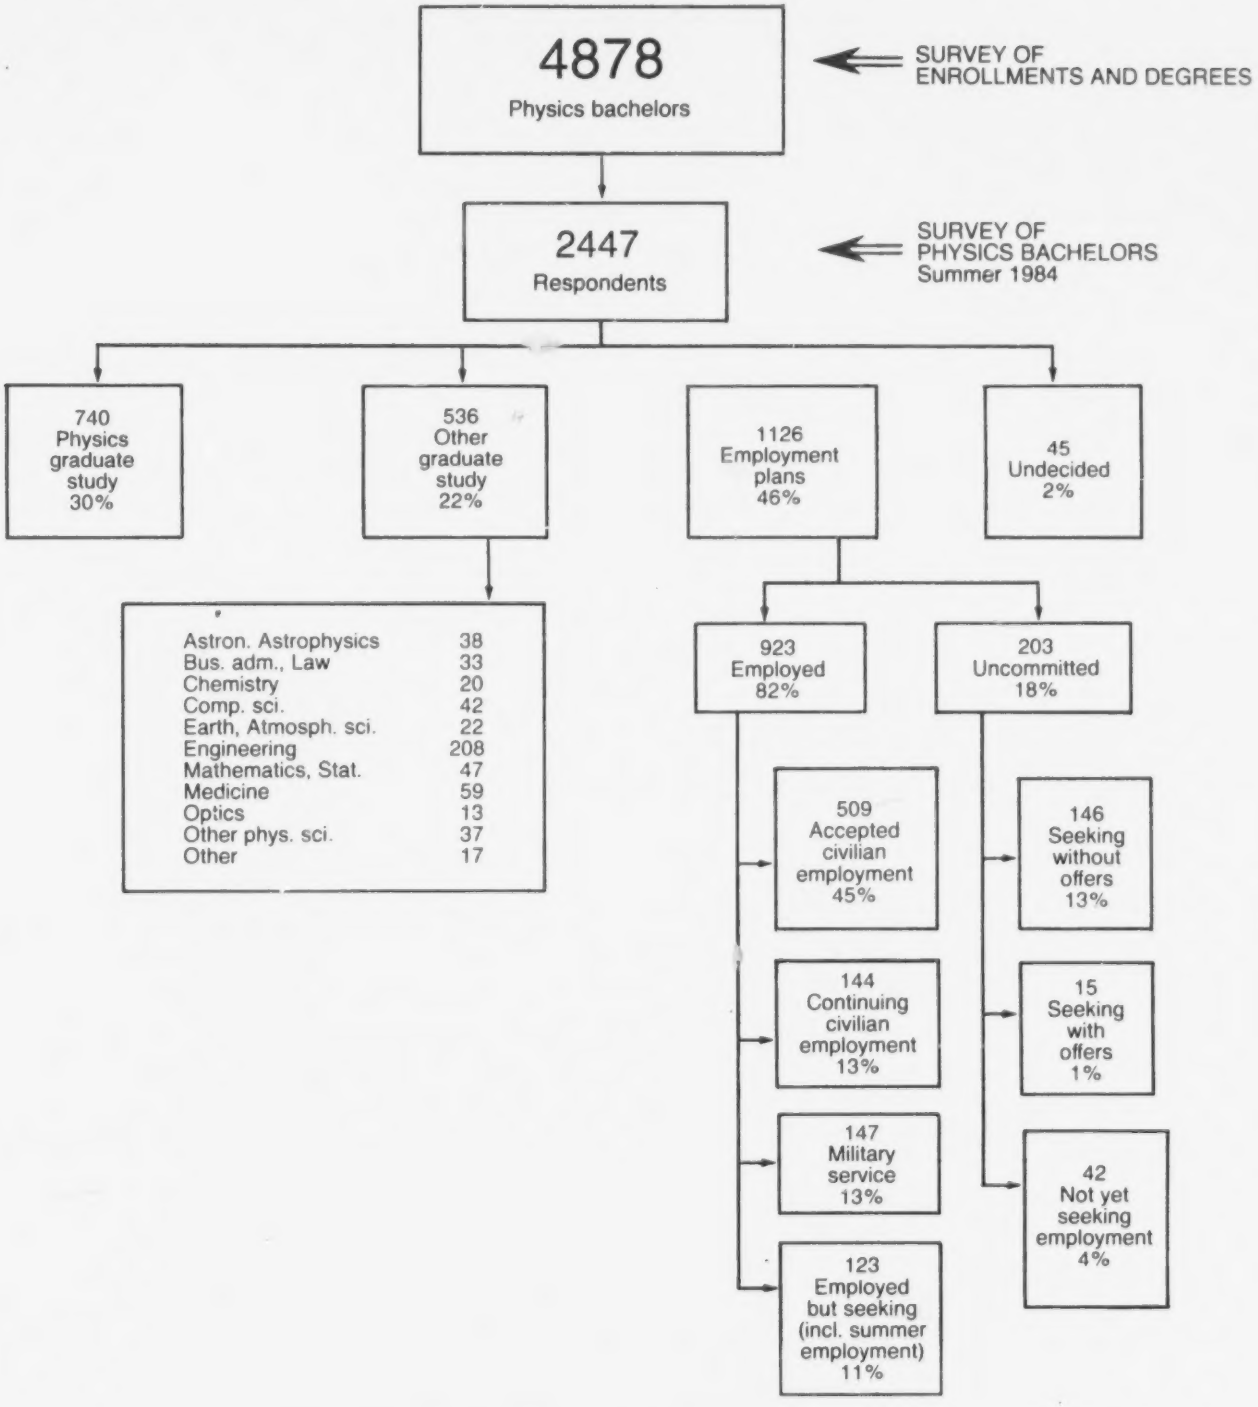
In regard to changes from the previous year, among the "other subjects of graduate study" engineering remained the one most frequently chosen and is followed by medicine, mathematics and computer science. Disciplines not obviously related to physics, such as business administration or law, have never attracted more than two or three percent of a year's graduates.

Table VII. Changes in employment outlook for new physics bachelors, 1974–1984.

Number of job offers at graduation	Summer 1974	Summer 1976*	Summer 1978	Summer 1980	Summer 1981	Summer 1982	Summer 1983	Summer 1984
0	18%	17%	10%	10%	10%	13%	11%	13%
1**	50	53	45	50	55	57	58	54
2 or more	32	30	45	40	35	30	31	33

**These figures have been revised from those presented in earlier reports to include military commitments.*
***Bachelors who enter the military service are included here.*

Fig. III. Postbaccalaureate plans of physics bachelors of the class of 1984.



A noteworthy change among the employment-oriented bachelors was a higher proportion of uncommitted graduates (18% compared with last year's 13%) which can be attributed to a three percentage-point difference in the group which is "not yet seeking employment" and a two percentage-point increase in those who are "seeking without offers." Although the group of "undecided" graduates has not changed in size in recent years, one can conclude from **Figure III** that there was an increase in graduates who are still in the process of deciding what to do; in spite of having accepted employment, they look for more appropriate positions.

Table VIII. Initial employment of physics bachelors, 1975–84.

Type of employer	Percentage of employed bachelors								
	1975–76	1976–77	1977–78	1978–79	1979–80	1980–81	1981–82	1982–83	1983–84

Total	100%	100%	100%	100%	100%	100%	100%	100%	100%

To get an accurate picture of where new physics bachelors find employment, we look at the types of employers reported by graduates in newly accepted potentially permanent positions. **Table VIII** compares the distribution of initial employers reported by the class of 1984 with those reported by earlier graduating classes and finds that industry continues to be the major employer, followed by the military and civilian government agencies. No significant change can be observed in the overall proportion of bachelors who accepted high school teaching positions, and low salaries may be one reason. According to **Table IX**, high schools pay the lowest median salaries. However a change from the previous year should be noted. The proportion of new women high school teachers doubled as their median starting salaries declined, while fewer men accepted high school positions at higher salaries than in the previous year. This phenomenon may be a reflection of the significant increase in the number of women among the employment-oriented graduates in the class of 1984. High school teaching allows them to utilize their physics training, a compensation to be weighed against a relatively low salary. For all employers combined the median starting salary rose 12%, an increase attributable to higher salaries offered by service industries and the civilian government agencies.

Tables VII through **IX** focus attention only on newly accepted employment thereby excluding the 144 graduates who had decided to remain with emplcyers whom they worked for before receiving their bachelor's degrees (see **Fig. III**). **Table X** on the other hand includes the group described as "continuing civilian employment," because its members also hold full-time potentially permanent positions whose work activities and employers are of interest. Since industry employs a majority of the bachelors, research, development and design are the most frequently reported work activities. While the ability to program is often a skill acquired as part of a physics bachelor's degree, technical writing is not. However 25 respondents, among the 1984 graduates did report technical writing as their major work activity and thus are listed in **Table X**.

Table IX. Starting salaries of physics bachelors, 1984.

*The employment of these 795 graduates includes both newly accepted positions as well as those in which graduates are continuing. Excluded are graduates in temporary and summer employment.
**Training paid for by the employer which includes 30 graduates sent to nuclear power school by the military.

ASTRONOMY

When one thinks of vocationally-oriented students, astronomy majors do not come typically to mind. The postbaccalaureate plans of the 1984 graduates show that almost 70% of them will enter graduate schools with their newly acquired astronomy bachelor's degrees.

The format of **Table XI** is similar to that of **Table II** for physics bachelors because both tables relate major characteristics of bachelor's degree recipients to their postbaccalaureate plans. The response rate of astronomy bachelors is slightly higher than that of the physics bachelors but **Table XI** presents numbers instead of percentages for the individual subgroups because of the small number of respondents in each.

General observations show that an undergraduate astronomy curriculum is primarily offered at Ph.D.-granting institutions and attracts higher proportions of women and double majors than physics does. Also astronomy bachelors tend to be younger than their physics counterparts.

Going back to the late 1970's **Table XII** indicates a general decline in the number of bachelor's degrees over the seven-

Table XI. Characteristics of astronomy bachelors, 1984.

year period. Consequently the number of respondents is decreasing proportionately thereby causing fluctuations in plans.

Figure IV offers additional details on the 76 astronomy bachelors and their postbaccalaureate plans. For example, 90% of those who go on to astronomy graduate study accepted assistantships or fellowships, and "other graduate study" generally includes many potential physicists. Of those who had accepted employment, only one bachelor evaluated his work activity as making extensive use of his astronomy training.

Fig. IV. Postbaccalaureate plans of astronomy bachelors of the class of 1984.
